

Assignment 13
CIS206 - W01 Spring 2026
Michael Brzozka

The problem I am facing is the need to organize and manage patient medical information in an object oriented way. In a real medical office, a patient may have several procedures, each performed by different practitioners and billed separately. Without a clear structure for data, it becomes difficult to track patient demographics, emergency contacts, procedures, and the total expenses. This program solves that problem by modeling a patient and their medical procedures using Python classes.

The scope of my solution includes the two main classes Patient and Procedure. The Patient class stores personal and contact information, while the Procedure class stores details about a specific medical procedure such as the name, date, practitioner, and cost. The program creates one Patient object and three Procedure objects, then prints all information along with the total charges.
